Improving Kyphotic Postures and Neck Pain in Young Adults: A Meta-Analysis of Exercise-Based Interventions

Mehjabeen Saeed, Fatima Zehra and Sehrish Aslam
Department of Physiotherapy, Jinnah University for Women, Karachi, Pakistan

ABSTRACT
The study aimed to review the findings concerning the effects of exercises on Cobb angle and pain in patients suffering from cervical pain caused by thoracic kyphosis. Two investigators separately conducted a systematic review of the electronic literature from 2018 till 2022. PubMed, MEDLINE, Web of Science, Science Direct, Cochrane Central Register of Controlled Clinical Trials, Google Scholar, and Scopus were among the electronic databases that were accessed. This meta-analysis included 5 studies, published between 2019 and 2022. A sample size of 261 patients; included in 5 studies were estimated on Cobb angle and pain. The between-groups pooled random SMD for Cobb angle and pain showed a larger effect size of -2.146 and -1.126, respectively. The findings suggested that physical therapy exercise may result in larger changes among the Cobb angle and neck pain of kyphotic patients.

Key Words: Exercise, Physical therapy, Cobb angle, Pain, Thoracic kyphotic angle, Conservative management.

INTRODUCTION
Musculoskeletal disorders affect around 1.71 billion people globally.1 The prevalence of spinal deformities rises with age, reaching an estimated 30 to 68% in the elderly,2 among which kyphosis is highly prevalent. The Cobb angle is used to identify thoracic kyphosis, an anteroposterior curve of the thoracic spine in the sagittal plane. Thoracic hyperkyphosis is characterised by a Cobb angle greater than 40 degrees.3 The disease not only affects older population but is also prevalent among the children with an estimated prevalence of 13.06%.4 The most noticeable symptom of hyperkyphosis is a rounded back caused by an excessive forward curvature of the spine.5 Through the cervicothoracic connection, the thoracic spine sustains the cervical spine and thus, affects its kinematics.6 In thoracic hyperkyphosis, the upper trapezius and pectoralis muscles are tense, whereas the cervical flexors and lower trapezius muscles are weakened, resulting in mechanical disequilibrium.7 Since alterations in sagittal thoracic orientation have been shown to affect the mechanical stress of the cervical spine and since decreased thoracic mobility has already been linked to shoulder and neck pain, it is plausible that thoracic articular therapy would restore local kinematics while also alleviating neck pain.

In a study by Lau et al., it was shown that there was an inverse relationship between pain intensity and increasing thoracic angle,8 although there was a significant association between neck discomfort and a greater upper thoracic angle.9 Treatment for kyphosis depends on the progression and severity of the deformity, the occurrence of neurological or cardiopulmonary complications, aesthetic concerns, and the deformity's degree while also taking into account the spine's residual growth.10 In the following situations, surgery for kyphosis is advised: alterations in the patient's neurologic condition, kyphotic angle ≥30°, and greater than 50% anterior vertebral height loss. Medical therapy for kyphosis consists of exercise, medication, and bracing.11 Sagittal spinal curvatures can be improved by systematic and sustained exercise.12

A number of physical therapy treatments are available for the management of kyphosis that include kinesiotaping, Schroth method, mobilisation, manipulation, strengthening and stretching exercises. According to a systematic evaluation of seven randomised controlled studies, exercise therapies aimed at increasing back extensor muscle strength resulted in modest improvements in clinical indices of kyphosis.12 Several randomised trials of spinal strengthening therapies had shown improvements in clinical assessments of kyphosis. Another study on hyperkyphosis in older adults published in 2017 found that spine strengthening exercise and postural training effectively reduced both clinical and radiographic measures of kyphosis in both men and women over the age of 65.13 Kyphotic posture and neck pain are prevalent among young adults, and can have a significant impact on their quality of life. However, the existing literature on exercise-based interventions for these conditions is incomplete. Moreover, there is not
a single study that conducted a meta-analysis to analyse the effects of conservative management on Cobb angle among kyphotic patients with cervical pain. Therefore, this study aimed to fill this gap in literature by conducting a meta-analysis of exercise-based interventions for improving kyphotic posture and neck pain in young adults. By combining the findings of several studies, this meta-analysis will provide a more comprehensive and precise estimate of the effect of exercise-based interventions. This will help guide healthcare professionals in selecting the most effective interventions for young adults with these conditions and provide directions for any future research. The aim of this meta-analysis was to determine the impact of exercise on thoracic kyphosis angle and chronic neck discomfort in kyphotic patients.

**METHODOLOGY**

Two independent investigators conducted a comprehensive search using the key terms kyphosis or Cobb angle or thoracic kyphosis angle or neck pain and exercise or physical activity or physical therapy or conventional physical therapy or physiotherapy or physical rehabilitation or Schroth method across 5 databases, including PEDro, PubMed, Web of Science, Cochrane and Library.

The PICOS approach was used to construct this question (population, intervention, comparison, outcome measurements, and research design). The meta-analysis included RCTs that would include patients with thoracic kyphosis and chronic neck pain, studies comparing physical therapy with a placebo or no intervention, and studies examining the effects of such treatment on TKA and pain that were written in English. Studies providing patient data on respiratory diseases, static, and dynamic balance were excluded.

From 2019 to 2022, two reviewers utilised the predetermined method to find studies for the current meta-analysis. The information that was extracted comprised the participants’ age and gender, sample size, and the interventions used in the experimental and control groups dosage used, outcome measurements, and results (Table I). The assessment of the risk of bias in the domains of selection, performance, detection, attrition, and reporting biases was performed using the Cochrane collaboration tool.14

Data was run in MedCalc statistical software, version 18.11.3. In random-effects model, the pooled impact was calculated using the continuous measurement standardised mean difference (SMD) method ($I^2$ at 95% CI). Hedges’ g statistics, SMD tables, and forest plots were used to evaluate the data. Cohen’s rule of thumb interpreted the findings, which indicated the values of 0.2, 0.5, and 0.8 to be of low, medium, and large effects, respectively. Cochrane’s Q statistic was used to determine the level of heterogeneity. The number was divided by Cochrane’s Q value to calculate $I^2$ and the degrees of freedom (DF) were removed to obtain a percentage value ($I^2 = Q/DF/Q$) of 0–100%, where 0% denoted no heterogeneity between the studies and higher values denoted a higher degree of variability. $I^2$ was used in order to make interpretation on the basis of random- and fixed-effect model ($I^2 \leq 50$ fixed effect, $I^2 \geq 50$ random effect).

**RESULTS**

This meta-analysis included 5 studies, all of which were published between 2019 and 2022. A sample size of 261 patients, included in 5 studies, were analysed in which the effects of physical therapy based management approaches for kyphosis associated with neck pain were estimated on Cobb angle and pain. After the search, n= 214 original articles were included initially. Further evaluation of the initially included articles led to the exclusion of duplicate and all those articles in which physical therapy management approaches were estimated after joint fusion surgeries and in which other variables were assessed, hence n=47 articles remained. Finally, after the further analysis, all articles published before 2019 and not available in the English language and for which no full-text was available even after contacting the authors and all paid articles were excluded. Hence, n=5 studies were included for analysis (Figure 1).

Five randomised controlled studies’ findings demonstrated that the physical therapy intervention considerably decreased Cobb angle in comparison to the control group. Standardised mean difference suggested an effect size of -2.146 in the random-effects model ($I^2 = 96.17\%; \ p < 0.001$) depicting a large effect size suggesting beneficial effects of physical therapy on Cobb angle among thoracic kyphotic patients with cervical pain (Table II).

—Bias at high risk, +Bias at low risk, ?Unknown risk of bias.
The results of five randomised controlled trials suggested that the physical therapy intervention in comparison to the control group considerably reduced the Cobb angle. As per the Cohen’s rule of thumb, a larger pool effect on SMD of -2.146 in random-effects model was obtained in the treatment group, as displayed in Table II. Moreover, forest plot at 95% CI was drawn to reflect the pool effects in the random effect model, as illustrated in Figure 2.

![Figure 2: Pool effect of studies determining the effects of exercises on Cobb angle among thoracic kyphotic patients with cervical pain.](image)

Five randomised controlled studies' findings demonstrated that the physical therapy intervention considerably decreased pain in comparison to control group. Standardised mean difference suggested an effect size of -1.126 in random-effects model ($I^2 = 91.43\%$; $p < 0.0001$) that depicted a large effect size suggesting beneficial effects of physical therapy on pain among thoracic kyphotic patients with cervical pain (Table III).

The results of five randomised controlled trials suggested that the physical therapy intervention in comparison to the control group considerably reduced the pain. As per the Cohen’s rule of thumb, a larger pool effect on SMD of -1.126 in a random effect model was obtained in treatment group, as displayed in Table II. Moreover, forest plot at 95% CI was drawn to reflect the pool effects in the random effect model, as illustrated in Figure 3.

Author’s judgment of risk of bias analysis based on guidelines of Cochrane are provided in Table IV, Figure 4. Randomisation was done in all studies suggesting a low risk of bias. Six studies revealed low risk of bias, two studies depicted unknown risk of bias, and only one study showed high risk of bias. Two studies did not mention about either participant or assessors’ blinding, and in one study, blinding was not done. All studies reflected low reporting bias risk.

**DISCUSSION**

The purpose of this meta-analysis was to investigate the effectiveness of exercise-based interventions in improving kyphotic postures and neck pain in young adults. The study of five trials included in this meta-analysis revealed evidences that physical therapy delivered effective results, as measured by greater effect size in this article. A significant decrease in Cobb angle was found among all the participants, with an effect size of -2.146 (CI -3.746 to -0.546, $p=0.0001$; random-effects model). Besides that, the impact of physical therapy on reducing pain had also been reflected on larger effect size in this study and had revealed an effect size of -1.126 (CI -2.056 to -0.196, $p=0.018$) signifying a positive effect of physical therapy in reducing pain as well. The findings are consistent with the previous research on the benefits of physical therapy for correcting postural abnormalities and reducing pain in young adults. A randomised controlled trial by Lee et al. showed that a 12-week exercise programme significantly improved thoracic kyphosis and reduced neck pain in the young adults. In 2020, a study was conducted on the effects of a combination of Schroth and Pilates exercises on various parameters in adolescents with idiopathic scoliosis, including the Cobb angle, angle of trunk rotation (ATR), chest expansion, flexibility, and quality of life (QoL). The study found that the combined exercises resulted in significant improvements in these parameters for adolescents with mild to moderate...
idiopathic scoliosis. Another study published in 2021 showed a low SMD of 0.31 at 95% CI on hyperkyphosis patients. There is scarcity of literature concerning the impact of different exercise regimes on cervical muscle strength and pain of thoracic kyphotic patients. As indicated in the study by Moon et al. in 2021, corrective exercises are more effective than the resistance exercises and traditional physical therapy in improving cervical muscle strength, and Cobb angle. The significance of clinical based rehabilitation for kyphotic patient is indeed of utmost importance as the changes in thoracic curvature can disturb the mechanics of proximal and distal joints, leading to cervical conditions in patients.

There are very few clinical trials in recent times that have analysed the effects of exercise on both kyphosis and cervical pain. Hence, the study did have some limitations. Due to the small number of research, the authors were unable to conduct sensitivity analysis on studies that solely recruited patients with hyperkyphosis. Sixty percent of the included studies either did not blind or mentioned blinding of outcome assessors. Additionally, the majority of the studies did not discuss negative outcomes, which raised questions about biased reporting. Future investigations should comprehensively assess the safety of exercise and other interventions in this population, even though only a few minor adverse events have been noted. The authors came across pertinent studies that fit the inclusion criteria but were deficient in some details.

CONCLUSION

Physical therapy exercise may result in larger changes among the Cobb angle and neck pain of kyphotic patients. More clinical trials need to be conducted on a larger sample size to get more generalised results.
