ABSTRACT

The levothyroxine absorption test for the assessment of pseudo-malabsorption in patients with refractory hypothyroidism has not been standardised. The aim of this observational study was to describe a protocol for levothyroxine (LT-4) absorption test in patients with refractory hypothyroidism, to report possible side effects and to emphasise the importance of pseudo-malabsorption in the differential diagnosis. The results of 10 patients, who underwent LT-4 absorption tests because thyroid stimulating hormone suppression could not be achieved despite the need for LT-4 >3 mcg/kg/day, were retrospectively analysed. When compared with basal free T4 (fT4), a statistically significant increase in fT4 was observed after the first hour (p=0.012). fT4 reached its peak level and plateau at the 4th hour. The fT4 peak level increased 3.25 times compared to baseline. The shorter LT-4 absorption test with low doses may provide an alternative method to the commonly used longer protocols with higher doses to rule out malabsorption.

Key Words: *Levothyroxine absorption test, Pseudo-malabsorption, Resistant hypothyroidism.*

INTRODUCTION

Hypothyroidism is a common endocrine disorder with an annual incidence of 1-2%. In patients with hypothyroidism levothyroxine (LT-4) requirement is approximately 1.2-1.6 mcg/Kg/day in most patients. In some patients, clinical and laboratory hypothyroidism cannot be managed in spite of high doses.¹ LT-4 malabsorption is a commonly known entity for some diseases. Common causes include gastrointestinal (GI), hepatic and pancreatic diseases, gastrointestinal surgical procedures, some drugs, dietary interactions, heart disease or pregnancy. However, the most common cause is poor/non-compliance with oral LT-4 treatment.² An objective way for differentiating patient's non-compliance from malabsorption is LT-4 oral absorption testing.³ Unfortunately, there are no vast number of case studies in the literature, indicating standardization of the test.

The aim of this study was to describe a protocol for a faster LT-4 absorption test in patients with treatment-resistant hypothyroidism, to report possible side effects and to emphasise the importance of a possible diagnosis of pseudo-malabsorption.

METHODOLOGY

In this study, the test results of patients, who underwent LT-4 absorption test at Endocrinology Clinic in the Kocaeli University Hospital, were evaluated retrospectively. The results between 05.09.2017-29.10.2019 were examined. The test was carried out after hospitalisation to monitor cardiac side effects and to make sure that the agent was administered. Ten patients were included in this study. The test was performed in the cases of overt hypothyroidism despite high dose LT-4 therapy of >3 mcg/Kg/day. Before the test, GI, liver and kidney diseases were excluded in all cases. Basal thyroid status, treatment doses, clinical and demographic findings were evaluated. After an overnight fasting, the patients were given about twice their usual LT-4 doses up to maximum 1 mg LT-4 (except for the pregnant patient). All drugs were given under supervision of nursing staff. Afterwards thyroid stimulating hormone (TSH) and free T4 (fT4) levels were measured at 0, 60, 120, 180, 240, 300 and 360 minutes. TSH and fT4 measurements were performed using electrochemiluminescence immunoassays. The patients were monitored in case of any cardiovascular side effects during and after the test. No complication related to LT-4 absorption test was observed in any patient in the following 24 hours.

All statistical analyses were performed using IBM SPSS for Windows version 20.0 (IBM Corp., Armonk, NY, USA). Shapiro-Wilk tests were used to test the normality of data distribution. Continuous variables were expressed as mean±standard deviation. Comparisons of normally distributed continuous paired variables between the times were performed using the paired sample t-test. A two-sided p value <0.05 was considered statistically significant.

Table I: The Diagnosis, basal thyroid status, LT-4 doses and test results of the patient.

Patient	Diagnosis	LT-4 dose	Basal TSH	Basal FT4	LT-4 test dose	Peak FT4	Nadir TSH
1	Hashimoto thyroiditis	300 (3.84 mcg/kg)	287	<0.25	600	0.87	259
2	Papillary thyroid cancer (operated)	350 (4.21 mcg/kg)	308	<0.25	700	1.69	283
3	Papillary thyroid cancer (operated)	400 (4.87 mcg/kg)	258	0.25	800	1.33	234
4	Hashimoto thyroiditis + pregnancy	500 (6.25 mcg/kg)	143	<0.25	600	0.38	130
5	Papillary thyroid cancer (operated)	800 (9.1 mcg/kg)	88	0.6	900	2.14	53
6*	Papillary thyroid cancer (operated)	300 (3.15 mcg/kg)	188	0.3	700	0.75	151
7	Papillary thyroid cancer (operated)	300 (7.1 mcg/kg)	66	0.55	900	1.45	62
8**	Papillary thyroid cancer (operated)	600 (3.06 mcg/kg)	59	0.29	1000	1.59	48
9**	Multinodular goiter (operated)	450 (6.42 mcg/kg)	10	0.55	900	1.69	8
10	Hashimoto thyroiditis	350 (4.11 mcg/kg)	31	0.57	700	1.58	24

ft4: free thyroxine TSH: Thyroid stimulating hormone. Reference Range: TSH 0.38-5.33 µIU/mL ft4 0.61-1.22 ng/dL *Uses 25 mcg of triiodothyronine additionally. **Had celiac disease and on a gluten-free diet.

RESULTS

A total of 10 patients were included in the study. The mean age of the patients was 44.4±10.8. Body mass index (BMI) of each patient was >25 Kg/m², and 7 patients were obese (BMI >30 Kg/m²). The mean TSH level was 143.8 ± 110.3 µIU/mL during pre-test evaluation. Mean daily dose of LT4 was 435 ± 161.7 mcg. LT-4 absorption test was performed with a standard protocol in all patients. For the pregnant woman, the test dose could not be doubled due to the pregnancy and therefore, normal ft4 levels could not be obtained. Daily LT-4 doses and levothyroxine absorption test results are listed below (Table I).

There was a statistically significant difference between the basal level of ft4 and ft4 level in the first hour after levothyroxine administration (p=0.012). The mean ft4 levels reached to normal range in the first hour following ingestion of LT-4. The peak level was seen in the fourth hour, but then the plateau (Figure 1).

Figure 1: Six-hour levothyroxine absorption test results: FT4 levels after oral administration of levothyroxine.

DISCUSSION

The authors aimed to define a standard protocol for levothyroxine absorption testing in patients with refractory hypothyroidism to rule out levothyroxine malabsorption. The absence of a standard approach causes some diagnostic difficulties. In this study, successful results were achieved with lower LT-4 test doses in a shorter period refraining from unnecessary drug exposure.

The increased LT-4 requirement can be seen in many cases. Ain *et al.* first revealed the theory of pseudo-malabsorption in 1991 after evaluating four refractory hypothyroid cases despite high doses of oral thyroid hormone replacement therapy.⁴ The LT-4 absorption test is used to distinguish patients' non-compliance from malabsorption.³ Although various protocols have been described in the literature, there is no gold standard method for LT-4 absorption test.⁵ If the levothyroxine absorption rate calculated using tT4 with a non-isotope method is ≥60%, it can be said that the absorption is normal. However, ft4 has largely supplanted tT4 in clinical practice. In studies, ft4 and tT4 showed high correlation even in patients with severe hypothyroidism.⁶ For this reason, ft4 has been suggested that it can be used instead of tT4 in LT-4 absorption test.⁶ The most preferred LT-4 dose is 1000 mcg as liquid or tablet form in the literature.^{3,5,6} However, we performed the 6-hour test with lower doses of LT-4. The authors determined the LT-4 test dose of each patient as twofold of their daily doses but not exceeding 1000 mcg. A significant increase in plasma ft4 levels was achieved demonstrating the adequate absorption of LT-4.

In patients with hypothyroidism, ft4 usually increases one hour after LT-4 administration and peaks at 2 hours.⁵ In another study, ft4 reached its peak level in two hours and the mean increase was 4.7 times that of the average basal level.⁷ In this study, ft4 reached the normal reference range at the first hour and the peak level at the 4th hour. The ft4 peak level increased 3.25 times compared to baseline.

In elderly patients with a history of cardiovascular disease, increased cardiac pressure load due to high thyroid hormone levels may lead to deterioration in cardiac functions.⁸ Successful responses to LT-4 absorption test was observed with lower doses of LT-4 than the doses reported in the literature. As a result, unnecessary dose was avoided, which is an important issue for the safety of the test, especially in patients with cardiovascular disease history. Both in the literature and in this study, there was no significant decrease in TSH levels in the 6-hour LT-4 absorption test. Therefore, we recommend ft4 measurements only in order to simplify the test and to be cost effective.

Celiac disease may cause hypothyroid patients to require higher doses of LT-4 to maintain euthyroid status.⁸ In this study, the patients with celiac disease had a good compliance to their gluten-free diets and showed significant increase in fT4 levels during the LT-4 absorption test.

Three cases of thyroid cancer with LT-4 pseudo-malabsorption have been reported in the literature and they were all female. Increased fT4 response to LT4 absorption test was observed in all three patients.^{9,10} Six of the 10 patients in this study were previously diagnosed with thyroid cancer. All patients with thyroid cancer were female but, it was difficult to conclude a causal relationship with such a small number of patients. It can be promisingly predicted that frequent discontinuation to provide endogenous hypothyroidism for radioactive iodine treatment and whole-body radioiodine scan might cause intestinal edema.

The patients are still coming to outpatient clinic controls. Although the LT-4 dose was increased in two patients, normalisation of TSH could not be achieved. Therefore, intravenous LT-4 was added to the treatment of these patients and euthyroidism was achieved in their follow-up. All patients are currently being followed up stably.

CONCLUSION

Low-dose LT-4 absorption test can be used successfully to avoid the effects of high-dose levothyroxine, especially in elderly patients and patients with heart disease.

ETHICAL APPROVAL:

All procedures performed in this study involving human participants were in accordance with the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards. The study was approved by the Ethics Committee of the University of Kocaeli with the project number KÜ GOKAEK 2019/124.

PATIENTS' CONSENT:

Informed consents were obtained from all individual participants included in the study.

CONFLICT OF INTEREST:

The authors declared no conflict of interest.
